

Methods that were not fully tested:

1. `evaluateData(Patient)` - it has almost exactly the same code with tested `evaluateData(Patient, int)`, which was created specifically for testing purposes.
2. `evaluateBloodPressure(ArrayList, ArrayList)` - parts which are not tested do not differ much from the tested ones (for example, if statements for low and high blood pressure have only different greater signs).
3. `evaluateData(Patient, int)` - the same case: parts which are not tested are, for example, adding cholesterol records to an `ArrayList`, which is done in exactly the same manner as with other medical records.
4. `main()` in `FileReader` - created for testing purposes, no need to test in separate unit.
5. `readData(DataStorage)`, `getFileNames(String)` - catch parts of `try...catch` statements are of no need to test.
